

The Design Metaphor

with Doren Recker, "How to Confuse Organisms with Mousetraps"; Helen De Cruz and Johan De Smedt, "Paley's iPod"

PALEY'S IPOD: THE COGNITIVE BASIS OF THE DESIGN ARGUMENT WITHIN NATURAL THEOLOGY

by Helen De Cruz and Johan De Smedt

Abstract. The argument from design stands as one of the most intuitively compelling arguments for the existence of a divine Creator. Yet, for many scientists and philosophers, Hume's critique and Darwin's theory of natural selection have definitely undermined the idea that we can draw any analogy from design in artifacts to design in nature. Here, we examine empirical studies from developmental and experimental psychology to investigate the cognitive basis of the design argument. From this it becomes clear that humans spontaneously discern purpose in nature. When constructed theologically and philosophically correctly, the design argument is not presented as conclusive evidence for God's existence but rather as an abductive, probabilistic argument. We examine the cognitive basis of probabilistic judgments in relationship to natural theology. Placing emphasis on how people assess improbable events, we clarify the intuitive appeal of Paley's watch analogy. We conclude that the reason why some scientists find the design argument compelling and others do not lies not in any intrinsic differences in assessing design in nature but rather in the prior probability they place on complexity being produced by chance events or by a Creator. This difference provides atheists and theists with a rational basis for disagreement.

Keywords: argument from design; cognitive biases; design stance; inference to the best explanation; intelligent design; natural theology; probabilistic inference; teleological reasoning

For many scientists and philosophers, David Hume's critique (1779) and Charles Darwin's theory of natural selection (1859) have definitely undermined the idea that we can draw any analogy from design in artifacts to design in nature. Yet the argument from design remains one of the most popular arguments for God's existence. It enjoys an enduring appeal, going back to as early as Plato's *Timaeus*, Cicero's *De Natura Deorum*, and Thomas Aquinas's *Summa Theologiae*. It garnered particular attention around the turn of the nineteenth century, with William Paley ([1802] 2006) as the best-known example. More recent formulations can be found in the work of Richard Swinburne (1968), Alvin Plantinga (1991), and proponents of intelligent design. Some, for example Jeffrey Wattles (2006), have argued that the appeal of the design argument can be explained by Aristotle's pervasive influence on Western philosophy and theology in his concept of nature as inherently purposive. Although cultural factors undeniably played an important role, we propose that the popularity of the design argument runs deeper and that its argumentative structure can be traced to evolved properties of the human mind.

Recent discussions of the design argument in philosophy and theology (such as Robertson 2007, letter 6) have paid relatively little attention to the psychological underpinnings that lead to the understanding and acceptance or rejection of this argument. In this essay we investigate the cognitive basis of the design argument, drawing on empirical studies from developmental and experimental psychology. We focus on two aspects: the tendency of humans to discern teleology in nature, and the way they intuitively assess probabilities. A better understanding of these aspects not only elucidates the lasting popularity of the design argument but also can help theists and atheists to construct a rational basis for disagreement.

We begin by outlining an analysis of the epistemic properties of the design argument. Next, we examine the cognitive basis of teleological reasoning and the design stance in children and adults. We then discuss the probabilistic aspects of the design argument. Finally, we explore why theists and atheists disagree on the plausibility of the argument.

THE ARGUMENT FROM DESIGN

The argument for the existence of a divine creator that is based on evidence of design in nature has recently enjoyed a revival in theology and philosophy. Biologist Richard Dawkins ([1986] 1991, 4–5) praises the argument for its explanatory coherence and intuitive appeal. Paley's image of the watch on the heath was certainly not the earliest formulation of the design argument, or even of the watch analogy, but its familiarity makes it a suitable starting point. The argument Paley presented in *Natural Theology* can be summarized as follows: When one encounters a watch, the complexity of this artifact and the interrelations of its parts lead to the inference

that it is the product of purposive design. From this Paley concluded that complexity in nature is also the product of a Designer, because proposing that it could have come about by chance would be absurd (Paley [1802] 2006, 7–15).

This argument has interesting epistemic properties: It is both an analogy and an inference to the best explanation. Analogies map the structure of a well-known domain (the source domain) onto a lesser-known problem (the target domain). In distant analogies the structures of source and target domains greatly differ in their basic ontological properties. The design argument is a distant analogy in that it maps the artifactual domain (source domain) onto the natural world (target domain). Artifacts exhibit goal-directedness in their design; they are intentionally created by designers who had their function in mind. Because organisms exhibit goal-directedness in their design, they must also be the product of a purposeful designer. Although this analogical structure has been attacked on the ground that it is inconclusive (Hume 1779; Frank 2004), distant analogies are well established in scientific practice as a way to gain insight into new problems. When the conceptual structure of the target domain is relatively unknown, as in the case of scientific discovery, scientists often resort to analogical reasoning of this sort as an epistemic action. Historical examples include Johannes Kepler's mapping of the properties of gravity onto the properties of light—the fact that sunlight dissipates with increasing distance between the Sun and the planets it is cast upon—to explain why planets farther from the Sun move more slowly, in this case, caused by a weakening of the gravitational force with increasing distance from the Sun (Gentner et al. 1997), and Darwin's analogy of a hundred thousand wedges to examine the force of natural selection (Millman and Smith 1997). A more recent example is the Swiss army knife analogy as a way to conceptualize the evolved structure of the human brain in evolutionary psychology (Cosmides and Tooby 1995, 88). The analogical structure of the design argument is thus epistemic; it is used to gain insight into an unfamiliar domain (God's creation). In many early versions, the design argument served a heuristic rather than a strictly argumentative purpose, as in the works of seventeenth-century natural philosophers such as Bernard Nieuwentijt and Antonie van Leeuwenhoek, who perceived design as a source of wonderment about nature.

Traditionally, design arguments had an inductive argumentative structure. They began with the empirical observation that all complex, functional objects of known origin were products of intelligent design. Then came the inductive step, in which one infers that what is true for some members of a class is true for all members. Hume (1779, part II, 56–60) dispensed with this way of reasoning by arguing that artifacts and biological organisms are too dissimilar to be classed together. When we see a house, we can reasonably infer that it has an architect or builder because we know

from experience that this particular effect flows from that particular cause. But we have no guarantee that the universe bears such a resemblance to a house as to invoke a Designer; we do not know how far our analogy is reliable. Indeed, because an object resembles other objects in that it has property *P* does not imply that it also resembles them in other respects. To suppose that it does is affirming the consequent, which is a logical mistake.

Although Paley did not mention Hume explicitly, the structure of his watchmaker analogy escaped this criticism by adopting a different strategy. It is an inference to the best explanation (IBE), which has the following structure:

IBE Given evidence *E* and a pool of plausible, potential explanations H_1, \dots, H_n of *E*, if H_i explains *E* better than any of the other hypotheses, infer that H_i is closer to the truth than any of these others. (Douven 2002, 359)

IBE enables us to probabilistically infer that a given hypothesis is closer to the truth than other hypotheses because it explains the available evidence better than rival explanations. In this probabilistic aspect, the design argument differs from deductive proofs for the existence of God, such as Anselm's ontological proof. IBE escapes Hume's critique because it does not rely on induction; it simply argues that there is no better explanation for order and complexity than design (Gliboff 2000). This fundamental probabilistic aspect of the design argument has received relatively little attention in the philosophical literature (but see Sober 2002).

Having established apparent design and probabilistic inference as two key properties of the design argument, we now examine the possible cognitive bases for its rational acceptability.

HOW WE INFER DESIGN

The Design Stance. To Paley, the conclusion that a watch is purposefully designed was self-evident. Our perception of its interrelated parts, formed and adjusted to each other—the coiled elastic spring, the flexible chains, the cogwheels—each fashioned out of the material that suits their intended function best, should lead us to infer that the watch must have had a maker who formed it for a specific purpose. Yet Paley acknowledged that such seemingly spontaneous inferences require contextual knowledge about the artifact under consideration: “it requires indeed an examination of the instrument, and perhaps some previous knowledge of the subject, to perceive and understand it” (Paley [1802] 2006, 8). In the case of the watch, Paley could infer the intent of the designer because he was familiar with the class of artifacts to which the watch belongs. But what would happen if he pitched his foot against an unfamiliar object, such as an iPod? Would he have inferred design as automatically as in the case of the watch? Its sleek shape, carefully integrated buttons, and intended function would have presented a puzzle to him. Unfamiliar artifacts can be so outlandish

that people can be led to believe that they are not the work of human designers. During World War II, when the indigenous inhabitants of Papua New Guinea were first confronted with Western goods from the American army, they believed that these were gifts of the ancestors. This led to the emergence of cargo cults, whose adherents are still trying to ritually lure airplanes into dropping more cargo, more Western goods (Frank 2004). And what to think of people who observe UFOs? Often these alleged spaceships are no more than military reconnaissance airplanes, crashing weather balloons, or bright planets. Nevertheless, people infer that the objects are intentionally designed by supernatural agents and by extraterrestrials respectively. To gain a better understanding of the design argument, it is therefore useful to examine how humans infer design, what constitutes necessary and sufficient conditions for something to be a product of design, and how creator and artifact are causally linked.

Evidence from developmental psychology suggests that design is not a feature we can objectively infer. Remarkably, neither complexity nor order is a necessary and sufficient condition to decide whether an object is purposefully created. For example, Susan Gelman and Karen Ebeling (1998) showed two-year-olds a stain vaguely resembling a bear. They told some subjects that the spot was created accidentally, by kicking over a bottle of paint, whereas another group learned that the shape was painted intentionally. Only the children in the latter group called it “a bear.” Thus the perception of the stain as representational or accidental depends critically on the prior information the children received on how it was brought about. In a similar experiment (Gelman and Bloom 2000), adults saw a variety of artifacts but were given two different accounts of how the objects came into being. In the unintentional version a piece of cloth was accidentally caught in a machine, resulting in holes being punched at regular intervals. In the intentional version, a person took scissors and carefully cut holes at regular intervals. Subjects were more prone to call the object “a belt” if they believed it was intentionally created. Apparently, design is in the eye of the beholder; our judgment that something is an artifact depends on our foreknowledge that the artifact was intentionally created. Once we are familiar with specific classes of artifacts, we can reasonably infer that a particular member of a class was created with the intention of belonging to this class. When we see a chair in a pile of rubbish, we conclude that the object was created to fulfill a specific function (to sit on) and to be of a specific class (chairs). This stance also provides useful inferences when we have to identify classes of nonutilitarian objects, such as ships in bottles. Although they will never sail, we still call them ships because the designer intended them to belong to this class of objects. The intimate relationship between design and intention was noted by Daniel Dennett (1987, 16–17) and Paul Bloom (1996) who argue that humans take an intuitive design stance: We use the designer’s intention to infer the class the object

belongs to. Paley relied on this inference in his assertion that the watch was a product of intentional design.

Conversely, knowledge of the designer's intention can help us to infer an object's intended function or identity. Bloom and Lori Markson (1998) conducted experiments in which three- and four-year-olds were shown featureless ovals that were purportedly drawn by a child with a broken arm who because of this could not draw well. The young subjects were told that these were drawings of chickens (three vertical ovals) and a pig (one horizontal oval). When prompted, the preschoolers effortlessly identified the pig, because they reasonably inferred that the artist would draw objects from the same category in the same way. Young children intuitively regard the creator of an artifact as having privileged knowledge about both its name and its intended function. This was illustrated by an experiment (Jaswal 2006) in which preschoolers saw objects that were given an anomalous label. The experimenter showed the children a key-shaped object and said "You are not going to believe this, but this is actually a spoon." They were willing to adopt the anomalous name only if the experimenter referred to the object as something he created, not as something he merely found. Recognizing that the creator of an artifact has the prerogative to name it marks an important step in the development of the design stance.

The intended function and identity of an object thus inextricably link the creator with the created object. This aspect of the design stance is particularly interesting in the case of broken objects. Although broken watches and fragile chairs cannot perform their intended function, we still name these objects watches and chairs because they were originally created to fulfill the intended function of their artifact class. When nine-year-olds and adults are presented with broken artifacts, they still label them according to their intended function, except if the transformation has changed the object beyond recognition (Gutheil et al. 2004). Paley voiced this intuition aptly when he stated,

neither . . . would it invalidate our conclusion, that the watch sometimes went wrong, or that it seldom went exactly right. The purpose of the machinery, the design, and the designer, might be evident, and in the case supposed would be evident, in whatever way we accounted for the irregularity of the movement, or whether we could account for it or not. . . . If by the loss, or disorder, or decay of the parts in question, the movement of the watch were found in fact to be stopped, or disturbed, or retarded, no doubt would remain in our minds as to the utility or intention of these parts. (Paley [1802] 2006, 8–9)

The human propensity of inferring design may be due to the distinct evolutionary history of our species. Humans rely to a unique extent on tools for their survival. Whereas other primates use mostly unmodified objects as tools, archaeological evidence for stone-knapping in hominids goes back as far as 2.6 million years (Semaw 2000). By adopting the design stance hominid children may have learned to use and fashion tools more

efficiently. Indeed, comparative studies of social learning in children and chimpanzees reveal stark contrasts in the way new tools are used. Whereas children take the intention of the person who demonstrates these tools as guidance, chimpanzees rely more extensively on the physical properties of the tools to figure out how they work (Horner and Whiten 2005). The design stance provides children with a useful heuristic to learn about their environment. It allows them to “ignore the actual (possibly messy) details of the physical constitution of an object, and [relying on] the assumption that it has a certain design, predict that it will behave as it is designed to behave under various circumstances” (Dennett 1987, 16–17). Without the design stance, we would not possibly learn to use and name hundreds of tools and other artifacts but would perhaps be limited to the less than ten tool types a typical community of wild chimpanzees entertains (Whiten et al. 1999). The hypothesis that the design stance is a product of natural selection, rather than the cultural product of Aristotelian teleology, finds support in the fact that it also occurs in non-Western cultures, even those where material culture is relatively sparse, like the Shuar, an Andean Native American culture (German and Barrett 2005), and that infants and young toddlers rely on it to learn the names of novel objects and how to use them (Casler and Kelemen 2007).

Intuitive Teleology. Whereas the design stance may have evolved for the purpose of rapidly categorizing and using artifacts, humans also possess a natural propensity for teleological reasoning. This propensity is most marked for biological entities, but it can apply to almost all categories of objects. Across cultures (see Barrett 2004), humans have the intuition that animals and plants possess adaptations that are self-beneficial, such as claws for defense or thorns for protection against being eaten. Young children, however, attribute purpose not only to artifacts and biological adaptations but also to entire organisms (What are lions for? “to go in the zoo”) and nonliving natural kinds like clouds (“for raining”)—a tendency termed “promiscuous teleology” (Kelemen 2004). Moreover, when given a choice between teleological and nonteleological explanations, preschoolers and elementary school children prefer teleological accounts. When asked whether rocks are pointy because of natural processes (“bits of stuff piled up for a long period of time”) or because of teleological functions (“so that animals could scratch on them when they got itchy”), children typically endorse the latter (Kelemen 2003). At ten to twelve years of age, the preference for teleological explanations lessens, probably because adolescents acquire elaborate coherent mechanistic explanations through schooling. Although mountains can be climbed, few adults would claim that mountains are there to climb on. This is because our learned knowledge that mountains are formed by tectonic activity or volcanism is incompatible with teleological explanations, where the function provides a sufficient reason for why the structure exists.

Remarkably, patients with Alzheimer's disease show a reemerging preference for teleological explanations. They think that rain is there so that plants and animals can have water to drink and grow, rather than the acquired explanation that rain occurs by water condensing into clouds and forming droplets (Lombrozo, Kelemen, and Zaitchik 2007). An increased tendency to teleology is also observed in people with little schooling such as Roma adults (Gypsies of central European descent). Formal education seems to reduce a preference for teleological explanations, but it cannot eradicate them. Indeed, when educated adults are forced to make speedy judgments, they too show a heightened acceptance of teleological explanations. When judging at a glance whether or not a statement is correct, they tend to endorse teleological, incorrect explanations, such as "The Sun radiates heat because warmth nurtures life" (Kelemen and Rosset 2009). Reasoning strategies observed in children persist into adulthood but may be masked by secondary explanatory strategies. Once these become impaired (in the case of Alzheimer's patients) or are unavailable (in the case of speedy judgments or lack of education), the intuitive, evolved strategies of childhood reemerge.

Although scientific education tends to lessen teleological reasoning, the tendency to apply teleology is not absent even among trained scientists. An analysis of the paleoanthropological literature (the study of human evolution) reveals that early theorists relied on extrascientific intuitive explanatory strategies. Until the late 1970s many paleoanthropologists thought that separate lineages of human races evolved toward an idealized endpoint, modern humans—a process denoted as orthogenesis, which is now uniformly rejected (De Cruz and De Smedt 2007).

Teleology is no longer considered a valid scientific principle in biology. It is hard to refrain from thinking that the eye's function is "for seeing," whereas it is more in tune with evolutionary theory to say that the eye's function can be described in terms of the effects it had for reproduction and survival in past organisms in which this structure evolved. Nevertheless, teleology is a useful heuristic to make sense of our everyday artifactual and biological environment. It enables us at a glance to see what a tool is for (a sharp edge for cutting, for example) or to categorize animals as dangerous or not (the presence of claws or fangs). As Immanuel Kant had already argued in his *Critique of Judgment* ([1790] 1987, part II, §66), we use teleological explanations because the concept of purpose makes living things and artifacts more intelligible to us. The central place of teleology in human cognition can perhaps explain why it remains an important philosophical and theological principle despite its lack of scientific plausibility.

The fact that our psychological propensities are sometimes at odds with scientific knowledge does not necessarily affect the rationality of our judgments. Not only are they often indispensable in everyday reasoning (our

understanding of artifacts would be seriously compromised without the design stance), but concepts such as *design* or *purpose* would be meaningless without them. Whether or not such concepts are also *scientifically* meaningful is to be empirically discovered.

Are Humans Intuitive Theists? Does the tendency to infer design also entail an inference to a Designer, as Paley and others have suggested? At this point, developmental and experimental psychological data do not present a unified picture. Tania Lombrozo and colleagues (2007) found that although Alzheimer patients reasoned more teleologically, they were not more likely than healthy control subjects to invoke God as an explanation. In a study that probed Dutch primary school children's intuitive theories on the origin of species (Samarapungavan and Wiers 1997), the answers clustered together in different categories, including spontaneous generation, Lamarckism, and pure essentialism (that is, animals and plants have always existed). Although many children made teleological inferences, only about ten percent made explicit reference to God or intelligent design. However, a comparable experiment in the United States by E. Margaret Evans (2001) found that the majority of ten-year-olds endorsed creationist accounts of the origin of species regardless of their religious background. Deborah Kelemen and Cara DiYanni (2005) obtained comparable results with British elementary school children, although the percentage of creationist accounts was significantly lower than with American subjects.

Several possible explanations may account for these findings. A strong position holds that humans are intuitive theists. In this view, creationism is a natural mode of reasoning that is altered only when children acquire explicitly nonreligious beliefs from their cultural environment. Jesse Bering (2006) defends this position, arguing that religious beliefs are biological adaptations that were directly selected to enhance cooperation, altruism, and group cohesion. A weaker position (Bloom 2007, for example) holds that religious belief itself is not innate but a byproduct of other cognitive adaptations such as agency detection and theory of mind. In this view, children acquire culturally transmitted religious beliefs easily because these key in on evolved propensities of the human mind. Here the step from design to Designer is not automatically made but needs to be made explicit, as Paley and others did. Support for this latter view comes from experiments in which Hindu (Barrett 1998) and Christian (Barrett and Keil 1996) college students had to recall stories about God. In doing so, they unconsciously distorted the stories to fit God into intuitive expectations they had about normal people, such as attending to only one person or one event at the same time. This indicates that representing an omniscient, omnipresent being is cognitively demanding and that expectations about human agents structure reasoning about divine agents. Another view, suggested by Taede Smedes as he read this essay, holds that intuitive theism

may be an evolved module, but it depends on external cultural circumstances for its development in the same way as the language faculty requires appropriate linguistic input to develop properly.

It is our belief that the experimental evidence does not support the view that there is an intuitive theism. Still required is an assignment of a probability to the existence of a Designer. In the next section, we look in more detail at the probabilistic aspects of the design argument.

INTUITIVE PROBABILITY: CAN CHANCE EVENTS PRODUCE ORDER AND COMPLEXITY?

The Annales and the Boeing. Joseph Butler (1736) already observed that all human reasoning is probabilistic: Because we are finite beings with knowledge that is restricted in time and space, we cannot claim absolute knowledge. From imperfect observations we regularly draw far-reaching conclusions. Humans are naturally endowed with the ability to detect statistical frequencies in their environment. (For a comprehensive overview, see De Cruz 2009.) This ability is not restricted to humans; it occurs in a wide variety of animal species, including those with relatively simple nervous systems such as bumblebees (Real 1991). Human infants use probability inference to learn about their environment, such as the statistical detection of recurring sound patterns to chunk streams of continuous speech into words, which is crucial for word learning (Aslin, Saffran, and Newport 1998). The design argument draws on our evolved ability to assess *posterior probability*, the probability that is assigned after the relevant evidence is taken into account. From the age of five onward, humans are fairly accurate in making such assessments (Giroto and Gonzales 2008). For example, if preschoolers are shown that more red than green chips are placed in a bag, they will correctly state that there is a higher chance that the experimenter will draw a red chip. However, if the experimenter says “I can feel that the chip in my hand is round” and proportionally more round chips are green, children will update their probabilistic judgments in favor of green.

How likely is it that the apparent design in nature was intentionally created or, alternatively, that it happened by chance? Early proponents of the design argument have taken their intuition that chance does not produce order as a starting point:

He who believes this may as well believe that if a great quantity of the one-and-twenty letters . . . were thrown upon the ground, they would fall into such order as to legibly form the Annales of Ennius. I doubt whether fortune could make a single verse of them. How, therefore, can these people assert that the world was made by the fortuitous concourse of atoms? (Cicero 45 B.C., book 2, § XXXVII)

Cicero discarded the atomists’ idea that chance collisions of elementary building blocks (atoms) formed the material world on the basis that chance

has a low probability of producing order. Assuming that the 21 letters of the Roman alphabet are equally distributed into his “great quantity,” the chance of the first letter’s falling in the correct place is $1/21$, the chance that the first two letters are correct is thus $1/21 \times 1/21 = 1/441$ (if the space is also treated as a letter, it would be $1/22 \times 1/22 = 1/484$). The chance that the letters would produce the approximately 7,000 characters of the 600 lines that survive of Ennius’ *Annales* (a now fragmentary epic poem on the history of Rome) is vanishingly small, being $1/21^{7000}$. Cicero’s intuition has been reiterated many times, including astronomer Fred Hoyle’s image of hurling around scrap metal at random and happening to assemble a Boeing 747. Although all arrangements of the scrap metal are, with hindsight, equally improbable, very few of them will fly; similarly, although all combinations of 21 letters are equally unique, very few of them will produce a legible text, let alone the *Annales*.

William Dembski (1998) has developed this inference as the basis for his defense of intelligent design. Although it is intuitively compelling, rejecting chance as an explanation for complexity and design is problematic because, as Elliott Sober (2002) notes, there is no probabilistic equivalent of *modus tollens*. In other words, we cannot state that

If hypothesis *H* were true, observation *O* would be highly improbable.

But *O*.

Therefore, *H* is not true.

The lottery paradox aptly illustrates this. Assume a fair lottery in which only 1 of 1,000 tickets is the winner. The probability of winning this lottery is very low. Yet winning the lottery does not cast doubt on its fairness. The law of likelihood in statistics stipulates that it is not the absolute value of the probability of data under a single hypothesis that is to be considered but rather how the probability values compare under different hypotheses.

The intuitive idea that improbability strengthens the existence of God is problematic in that it tacitly relies on an analogy between human and divine agency. When deciding whether human design or chance is responsible, we rely on empirical knowledge of what human agents in fact do. In an example from Kenneth Himma (2005), adapted from Dembski (1998), suppose a political candidate’s name appears first on the lists of voting ballots 40 out of 41 times. The probability of such an event’s occurring by chance is very small. But when we suspect that a county clerk rigged the list, we rely on two pieces of tacit knowledge: that undecided voters are more likely to choose the first on the list, and that the county clerk wants a particular candidate to win. Being an intelligent agent, it is not unlikely that he rigged the list. We also know of cases in which ballots *were* tampered with to win an election. Hence the hypothesis that the name was placed first 40 out of 41 times by design rather than mere chance becomes very plausible indeed.

In the case of divine action, however, we do not have empirical knowledge to draw upon, and thus no assumptions can be made about what God would or would not do. It is not possible to accord prior probabilities to the existence of God on the basis of empirical evidence. Without the necessary background data to make the design argument an IBE, this argument relies on an analogy between human and divine agency. Again, this version of the design argument becomes an argument from analogy. As we have seen, this was successfully attacked by Hume, and it was precisely for this reason that Paley recast the argument from design into an IBE.

Probability and Inference to the Best Explanation. The reliability of IBE as an abductive strategy depends on the amount and quality of the data and the relevance of the data to the conclusion. If insufficient evidence is available, IBE may well lead us to choose “the best of a bad lot” (van Fraassen 1989, 143). In fact, the bad-lot argument even applies if one has all the possible evidence, because one may simply have failed to conceive of the true theory with this evidence in hand. If each letter that falls correctly is selectively retained, we need at most $21 \times 7,000$ trials to complete what is now left of the *Annales*. Cicero, being unacquainted with the principle of cumulative selective retention, did not envision this possibility. Dawkins ([1986] 1991, 46–48) uses a similar analogy to illustrate this point: Whereas one monkey could not possibly type a sentence from Hamlet, selective retention of keystrokes by many typing monkeys would solve the problem.

When using an IBE strategy, however, most modern versions of the design argument do not take natural selection and its principle of cumulative selective retention into account as a viable explanation. Dembski (1998), for example, holds that regularity, chance, and design exhaust the possibilities, thereby sidestepping the combination of chance and regularity that is natural selection. To be sure, in 1802 natural selection was not in the pool of possible explanations. However, as Sander Gliboff (2000) demonstrates, Paley did have a range of alternative materialist explanations, of which we mention three. First, necessity: Because everything has to have some form, it may as well be the present form; for example, the eye is the actual realization of the possible ways to fill an eye socket. Second, he considered infinite trial and error: Given an infinite time and universe, every possible configuration of matter could be produced, some of which turned out to be viable life-forms that persisted and reproduced—an interesting precursor to the concept of natural selection. Third, he discussed the claim that parts of organisms could arise before their function was determined, a forerunner of exaptation theory (Paley [1802] 2006, 38–41).

These alternatives were being explored and hotly debated in Paley’s time by early evolutionists such as Georges-Louis Leclerc, Comte de Buffon,

Denis Diderot, and Paul-Henri Thiry, Baron d'Holbach. Paley seems familiar with these authors, as he mentioned Buffon explicitly and others implicitly. Next to these, he briefly discussed the special biological forces or organizing principles proposed by the Göttingen school of German biologists, such as Johann Friedrich Blumenbach, Carl Friedrich Kielmeyer, and Johann Christian Reil (Paley [1802] 2006, 218–25). Although rejected now, their Newtonian approach to biology in which they stipulated forces acting on biological entities (analogous to physical forces acting on physical entities) was conceivable and widely accepted at the time. The idea proposed by atomists such as Democritus and Lucretius that very improbable things may happen in an infinite universe has its modern statistical formulation in Persi Diaconis and Frederick Mosteller, who write that “with a large enough sample, any outrageous thing is likely to happen” (1989, 859).

What led Paley to reject these alternatives? His answer was that the purported natural propensities required intelligent design: “I am unwilling to give to it the name of an atheistic scheme . . . because, so far as I am able to understand it, the original propensities and the numberless varieties of them . . . are, in the plan itself, attributed to the ordination and appointment of an intelligent and designing Creator” ([1802] 2006, 224–25). One could dismiss this as a circular argument in that he rejected naturalistic explanations because they point to a Designer, the proposition that had to be proven. We want to argue that it can likewise be seen as arising out of the high probability Paley accorded to the existence of God. As we argue in the next section, the likelihood of data can be meaningfully assessed only in relationship with hypotheses, which are accorded a prior probability.

A RATIONAL BASIS FOR DISAGREEMENT

If humans are prone to discern design and teleology in nature, why do some find the design argument more compelling than others? This may be due not to intrinsic differences in the way design and teleology are discerned but to differences in the prior probability people place on the existence of a Designer.

An interesting way to approach this problem is through an examination of how humans regard coincidences. For Thomas Griffiths and Joshua Tenenbaum (2007), an event is a coincidence if it is judged to have a lower probability of occurring under our current theory of how the world works than under an alternative hypothesis. Coincidence plays an important epistemic role in scientific discovery: The meteorologist Alfred Wegener noted that the coastlines of West Africa and South America fit into each other like puzzle pieces, that their geological strata matched, and that the distribution of species on both sides of the Atlantic was highly correlated. He

thought that this pattern was not a mere coincidence but that these continents were once joined and had drifted apart. In the nineteenth century, physician John Snow noted that cholera outbreaks in London tended to cluster at public water pumps and inferred that this was not a coincidence but provided evidence for his theory that cholera was transmitted through polluted water (rather than bad air, the then favored theory).

These examples suggest an intimate connection between coincidence and evidence. A *coincidence* occurs when the likelihood ratio in favor of an alternative theory is insufficient to overwhelm the prior odds against it. A coincidence becomes evidence when the likelihood ratio in favor of an alternative theory overcomes the prior odds against it and leads us to accept that alternative theory. Because people differ in the prior probabilities they assign to alternative hypotheses, what is a coincidence to one person can be considered compelling evidence by another.

In the case of the design argument, the competing hypotheses are H_{mat} (purposive and complex structures arose strictly through natural, material causes) and H_{deo} (design as the result of a Designer). In the framework of H_{mat} , the occurrence of ordered complexity and apparent design presents a coincidence. Given that chance events tend to produce disorder, the probability of this occurrence is extremely low. Darwin's theory of natural selection has successfully solved this dilemma, because it relies on a combination of chance and lawlike processes. Indeed, no other naturalistic theory can explain why living things are improbably complex, why the interrelationships between their parts are highly functional, and why they exhibit features that enhance their probability of surviving and reproducing in their environment. Proponents of H_{mat} can find epistemic justification in Darwin's explanation of design. To justify why they favor their view rather than H_{deo} , they can cite examples of maladaptedness and appeal to ontological parsimony because their explanation is restricted to observable, causal physical processes. In H_{deo} the occurrence of design is not improbable, because this theory explicitly proposes a Designer who made the universe orderly and purposeful. Under these epistemic circumstances, but not under H_{mat} , design in nature becomes corroborative evidence for the existence of a Creator. Next to this, natural theologians can also appeal to ontological parsimony, because it reduces many kinds of explanation to one under H_{deo} (Swinburne 1968).

This model of prior probabilities explains three puzzling facts. First, it explains why evolutionary thinkers writing before 1859 did not accept natural theology's design argument. Even in Paley's time, not everyone was led to accept H_{deo} , although the arguments in favor of natural theology were widespread. Early evolutionists, including Erasmus Darwin and biologists of the Göttingen school, sought to describe biological forces that could assemble complexity in the same way as Isaac Newton had done for mechanics. These authors had a strong commitment to a physicalist world-

view leading them to adopt the view that H_{deo} was unlikely, even though they did not have a compelling causal explanation for the apparent design. Second, it explains why the design argument, despite its intuitive appeal, fails to convince nonbelievers. As long as plausible naturalistic explanations for design in nature are available, the design argument will fail to overturn their prior beliefs. Third, it may elucidate why well-established scientific data do not persuade believers of design of the opposite. This is shown paradigmatically in the United States, where everyone has access to scientific education, yet creationism and intelligent design are widespread, and many express severe distrust of evolutionary theory (see Miller, Scott, and Okamoto 2006). The epistemic force of the prior probabilities we accord to competing hypotheses is an important element in scientific and other formalized ways of reasoning. It can explain why scientists are unwilling to let go of a cherished theory even in spite of overwhelming evidence against it, as already described by Thomas Kuhn (1962). For theists, design in nature provides compelling circumstantial evidence for the existence of a Creator. Take as an illustration the Thomistic tradition, which emphasizes the role of understanding and knowledge (*scientia*) in belief. In this view, a successful natural theology would start out from self-evident premises, proceed by valid arguments, and reach the conclusion that there is a person such as God (Plantinga 1991). As we have seen, humans are prone to discern design and teleology in nature. Within the epistemic context of H_{deo} , the perceived design in nature that is a universal feature of human cognition can be taken as a self-evident premise from which the existence of a Creator can be argued. It is not a stand-alone argument that can convince those who do not believe in God (see also Himma 2005), especially since plausible naturalistic explanations have become available.

IS THERE STILL A PLACE FOR THE DESIGN ARGUMENT?

Undeniably, the power of the design argument as an inference to the best explanation has been seriously weakened since Darwin and Alfred Wallace independently came up with natural selection as a naturalistic explanation for design. Given that the combination of random events and selective retention can explain most of the apparent design around us, can theologians still reasonably invoke design? Misrepresenting or altogether neglecting natural selection is the strategy most commonly adopted by intelligent-design proponents. Intelligent design is not a very desirable position for theologians to take, however, because it makes scientific claims that need to be evaluated by scientific standards. As a scientific research program, it fails because its hypothesis of a Designer is too vague and too general to count as a scientific hypothesis; it cannot be used as a basis for empirical testing. Even concepts such as irreducible complexity are too broad and too vacuous to be investigated by biologists; to date, there are no satisfying

models of complexity that allow for investigation by empirical, quantitative methods. Moreover, using scientific standards to argue for divine action is a category mistake, because God is not an immanent cause like other natural causes (Smedes 2008).

The most productive way for theologians and scientists to look at the argument from design is to treat it as a metaphysical rather than a scientific principle. Within this perspective, we think there are at least two cases in which a design position is still defensible. A first case is presented by a position that endorses evolutionary biology but argues that God intervenes occasionally to fashion structures that could not have arisen through natural selection. In this position, one endorses intelligent design as a philosophical position but not as a scientific research program that conceptualizes evolution and design as competing scientific explanations. Theologically, it follows a distinction that is commonly made between God's general actions (which pertain to the universe as a whole and can be seen in the laws that govern physical, chemical, and biological processes) and special actions (which lie beyond normal physical processes). Whereas natural selection and other evolutionary processes belong to the former category, occasional design or intervention in these belongs to the latter.

Jeffery Johnson and Joyclynn Potter (2005) propose that human natural language may be the product of purposive creation. They base their argument on the fact that adaptationist explanations require a plausible reason for why the adaptation evolved. Adaptations evolve in response to specific selective pressures and enhance the survival and reproduction of their bearers. For language, there are as yet no persuasive adaptationist explanations. We do not know what language is an adaptation for or how and when it evolved. Despite the proliferation of adaptationist stories on the origin of language, such as social grooming, technological intelligence, cooperative hunting, and sexual selection, none of these hypotheses has been able to substantiate itself into a theory. This leads Johnson and Potter to infer to the best explanation that purposive design brought language into being. Their position is distinct from intelligent design in that they explicitly endorse evolutionary theory as the best explanation for complexity in the living world.

A second, perhaps stronger, case (because it does not rely on a God of the gaps) is found in scientists and theologians who regard design and evolution as complementary rather than mutually exclusive explanatory frameworks. Watchmakers do not build watches from scratch but rather rely on the gradually accumulated innovations in timekeeping technology, which we can trace back to sundials and waterclocks, to the introduction of the spring, to the modern digital watch. Upon close scrutiny, very few inventions appear *de novo*; most are the result of a gradual and cumulative retention of favorable variations (Basalla 1988). The streamlined design of Polynesian canoes, which is close to optimum, can be traced through ar-

chaeological and historical data as the gradual and unconscious retention of favorable variations, with the perilous ocean as the selecting agent (Rogers and Ehrlich 2008).

These insights on the origin of artifacts can be extended to divine design. Nineteenth-century botanist Asa Gray defended the view that natural selection is an “a-fortiori extension to the supposed case of a watch which sometimes produces better watches, and contrivances adapted to successive conditions, and so at length turns out a chronometer, a town clock, or a series of organisms of the same type” (Gray 1888, 57). Cell biologist Kenneth Miller argues that God has initiated natural selection and other natural evolutionary processes as an indirect way to create complexity and design. For him, the undetermined nature of evolution through natural selection and other natural processes enabled the evolution of truly free, truly independent beings (Miller [1999] 2007, 213, 238, 253). Theodosius Dobzhansky, one of the founding fathers of the modern synthesis, wrote, “The organic diversity becomes . . . reasonable and understandable if the Creator has created the living world not by caprice but by evolution propelled by natural selection. . . . Evolution is God’s, or Nature’s, method of Creation” (Dobzhansky 1973, 127). This position is stronger than intelligent design, because proponents of the latter—who see natural and supernatural causes as competing explanations for complexity in the living world—in many cases need to acknowledge that natural selection is the better explanation. This problem is avoided when one allows for the possibility that evolution and design are not mutually exclusive.

On the basis of modern evolutionary theory it is not possible to reject either H_{mat} or H_{deo} . Both positions depend on prior probabilities that are assigned on the basis not of scientific evidence but of metaphysical principles. It is interesting that both positions, physicalism and naturalistic theism, already existed in the earliest stages of evolutionary theory. Whereas Darwin and Thomas Huxley did not provide room for God in their explanatory frameworks, Wallace and Gray were theists who treated divine action as complementary with a scientific worldview, not as a competitor. Wallace, while continuing to endorse natural selection as the chief principle guiding the evolution of plants and animals, invoked intelligent design for the human mind: “The brain of pre-historic and of savage man seems to me to prove the existence of some power, distinct from that which has guided the development of the lower animals through their ever-varying forms of being” (1871, 343). Martin Fichman (2001) aptly argues that Wallace’s theism, rather than an about-face, was an integral part of his evolutionary thinking. Today, both schools of thought continue to exist side by side, with Dawkins and Dennett as examples of strict materialists and Miller and Simon Conway Morris as proponents of theistic evolution.

To summarize, the argumentative structure of the design argument can be traced back to evolved biases of the human brain. It relies on the design

stance, which leads us to treat complex and purposive structures as the product of design, and on intuitive teleology, the propensity of humans to discern purpose in nature. These cognitive biases are universal, although they can be masked by formal education or strengthened by religious upbringing. The step from design to Designer is perhaps more explicit, and relies on an inference to the best explanation. The plausibility of this inference relies on the prior probability one places on the existence of God. By making these differences in prior probability more explicit, theists (natural theologians, biologists, and philosophers) and physicalist scientists and philosophers have a rational basis for disagreement.

NOTE

Elements of this article were presented at a colloquium on evolutionary theory and intelligent design jointly organized by Ghent University and the Belgian Institute of Natural Sciences, Brussels, Belgium, 20–21 August 2008. We express our gratitude to Igor Douven and Taede Smedes for their elucidating comments and suggestions to an earlier version of this essay and to the anonymous reviewers for their helpful suggestions. This research is supported by grant 3H070815 from the Research Foundation Flanders and grant COM07/PWM/001 from Ghent University.
